WATER PENETRATION

VELOCITY THROUGH FREE AREA fpm (m/s)

Both maximum recommended free area velocity and beginning of water penetration are 1009 fpm at standard air - .075 lbs per cu ft. The above water penetration data is based on mill finish, 48" x 48" test size per AMCA Standard 511.

Openings that require multiple louver panels in both width and height will require internal structural supports. It is recommended that large openings be divided with structural members so that the louvers will span either width or height with a single panel. Unusually high wind loading may require structural supports on non-multiple wide and multiple high assemblies. **Structural supports and mounting accessories are not supplied as a standard.**

Example: Given: 15000 CFM design flow

Step #1:

$$\text{min. free area} = \frac{\text{Design CFM}}{\text{Max. Recommended Velocity}}$$

$$= \frac{15000}{1009} = 14.87 \text{ sq ft}$$

Step #2: From the free area table above, the approximate louver size is 84" x 48" = (15.64 sq ft)

Below is an explanation of how to use the AMCA Performance data for the recommended free area velocity of 1009 fpm (5.12 m/s).

To determine minimum free area required for louver:

Step #1: Divide the required CFM flow by the maximum recommended free area velocity.

Step #2: Select the most desirable louver size from the free area table that meets the minimum free area requirement.

Step #3: Compare specified performance to the certified water penetration and pressure drop ratings.
